**Phase Transitions**

1. *Dieterici's equation:* A gas obeys Dieterici's equation of state:

$$P(v - b) = k_B T \exp\left(-\frac{a}{k_B T v}\right),$$

where  $v = V/N$ .

- (a) Find the ratio  $Pv/k_B T$  at the critical point.
- (b) Calculate the isothermal compressibility  $\kappa_T$  for  $v = v_c$  as a function of  $T - T_c$ .
- (c) On the critical isotherm expand the pressure to the lowest non-zero order in  $(v - v_c)$ .

2. *2d Coulomb Gas:* Consider a classical mixture of  $N$  positive, and  $N$  negative charged particles in a *two dimensional* box of area  $A = L \times L$ . The Hamiltonian is

$$\mathcal{H} = \sum_{i=1}^{2N} \frac{\vec{p}_i^2}{2m} - \sum_{i < j}^{2N} c_i c_j \ln |\vec{q}_i - \vec{q}_j|, \quad ,$$

where  $c_i = +c_0$  for  $i = 1, \dots, N$ , and  $c_i = -c_0$  for  $i = N + 1, \dots, 2N$ , denote the charges of the particles;  $\{\vec{q}_i\}$  and  $\{\vec{p}_i\}$  their coordinates and momenta respectively.

- (a) Note that in the interaction term each pair appears only once, and that there is no self interaction  $i = j$ . How many pairs have repulsive interactions, and how many have attractive interactions?
- (b) Write down the expression for the partition function  $Z(N, T, A)$  in terms of integrals over  $\{\vec{q}_i\}$  and  $\{\vec{p}_i\}$ . Perform the integrals over the momenta, and rewrite the contribution of the coordinates as a product involving powers of  $\{\vec{q}_i\}$ , using the identity  $e^{\ln x} = x$ .
- (c) Although it is not possible to perform the integrals over  $\{\vec{q}_i\}$  exactly, the dependence of  $Z$  on  $A$  can be obtained by the simple rescaling of coordinates,  $\vec{q}_i' = \vec{q}_i/L$ . Use the results in parts (a) and (b) to show that  $Z \propto A^{2N - \beta c_0^2 N/2}$ .
- (d) Calculate the two dimensional pressure of this gas, and comment on its behavior at high and low temperatures.
- (e) The unphysical behavior at low temperatures is avoided by adding a hard-core which prevents the coordinates of any two particles from coming closer than a distance  $a$ . The appearance of two length scales  $a$  and  $L$ , makes the scaling analysis of part (c) questionable.

By examining the partition function for  $N = 1$ , obtain an estimate for the temperature  $T_c$  at which the short distance scale  $a$  becomes important in calculating the partition function, invalidating the result of part (c). What are the phases of this system at low and high temperatures?

**3. One dimensional gas:** In statistical mechanics, there are very few systems of interacting particles that can be solved *exactly*. Such exact solutions are very important as they provide a check for the reliability of various approximations. A one dimensional gas with short-range interactions is one such solvable case.

(a) Show that for a potential with a hard core that screens the interactions from further neighbors, the Hamiltonian for  $N$  particles can be written as

$$\mathcal{H} = \sum_{i=1}^N \frac{p_i^2}{2m} + \sum_{i=2}^N \mathcal{V}(x_i - x_{i-1}).$$

The (indistinguishable) particles are labelled with coordinates  $\{x_i\}$  such that

$$0 \leq x_1 \leq x_2 \leq \cdots \leq x_N \leq L,$$

where  $L$  is the length of the box confining the particles.

(b) Write the expression for the partition function  $Z(T, N, L)$ . Change variables to  $\delta_1 = x_1$ ,  $\delta_2 = x_2 - x_1$ ,  $\cdots$ ,  $\delta_N = x_N - x_{N-1}$ , and carefully indicate the allowed ranges of integration and the constraints.

(c) Consider the Gibbs partition function obtained from the Laplace transformation

$$\mathcal{Z}(T, N, P) = \int_0^\infty dL \exp(-\beta PL) Z(T, N, L),$$

and by extremizing the integrand find the standard formula for  $P$  in the canonical ensemble.

(d) Change variables from  $L$  to  $\delta_{N+1} = L - \sum_{i=1}^N \delta_i$ , and find the expression for  $\mathcal{Z}(T, N, P)$  as a product over one-dimensional integrals over each  $\delta_i$ .

(e) At a fixed pressure  $P$ , find expressions for the mean length  $L(T, N, P)$ , and the density  $n = N/L(T, N, P)$  (involving ratios of integrals which should be easy to interpret).

Since the expression for  $n(T, P)$  in part (e) is continuous and non-singular for any choice of potential, there is in fact no condensation transition for the one-dimensional gas. By contrast, the approximate van der Waals equation (or the mean-field treatment) incorrectly predicts such a transition.

(f) **(Optional)** For a hard sphere gas (as in PS#6, problem 3, or PS# 8, problem 2, part (d)) calculate the equation of state  $P(T, n)$ . Compare the excluded volume factor with the approximate result obtained in PS#3, and also obtain the general virial coefficient  $B_\ell(T)$ .
